NETWORK BASED PROGRAMMABLE MEDIA MANIPULATOR

RELATED APPLICATIONS

- This application claims priority to U.S. Provisional Application No. 60/020,094, filed June 21, 1996, the contents of which is incorporated herein by reference in its entirety.

BACKGROUND OF THE INVENTION

In a client-server network, on one hand there are clients, typically personal computers, IBM-compatible computers and/or UNIX workstations, for example, equipped with information browsers. On the other hand, there are data servers and compute servers. Data servers are computers with a large storage capacity containing information in different media formats: data records, plain text documents, word processing documents, still pictures, compressed audio and video, and executable files, for example. Compute servers are computers that carry out intensive computational tasks that would typically require too much time for the client to complete. Each compute server might use a single or many processors to complete the given task.

Users interact with their clients in a natural way with a mouse, keyboard, screen, printer, or by some other input/output device. The users need not be concerned about what happens after they make their selection within their clients. Clients then make service requests to geographically dispersed servers. Upon receiving requests from the clients, the servers

-2-

perform the desired operations and return the retrieved or computed media stream back to the client for display.

5 SUMMARY OF THE INVENTION

The present invention is connected into the ubiquitous two-tiered client-server network of computers. It is designed as a middle layer, middleware, between the clients and the remote data servers. It transforms the network into a more flexible three-tiered configuration. Requests generated by the clients for media objects from media resources are routed to the media manipulator. It processes the requests and determines if the media objects may be found locally, either cached in the media manipulator itself or in local/remote data servers. When the media objects are obtained, the media manipulator can be used to perform operations on those objects such as format translations, to apply protective mechanisms for the clients such as virus scanning, to speed communications between the remote servers and the clients using compression operations, or perform compute operations for the clients.

25 In general, according to one aspect, the invention features a middle-ware computing system. It includes a network access system that supports communications with media resources and client computers and a media manipulation system that operates on media objects received from the media resources via the network access system prior to forwarding the media objects to the client computers.

30 In specific embodiments, a parser is used to identify different media types within the media objects

-3-

so that service devices may be called to operate on the media types. In one example, the parser searches for images in the media objects and service devices include an image compressor for performing data compression or 5 pornography detection on the images. The parser can also search for executable or data files in the media objects and the service devices then called to perform virus scanning or format conversion, respectively.

10 In further specifics, a cache is used to store media objects. A media flow manager receives requests for media objects and checks for the presence of the media objects in the cache to preclude the necessity of obtaining the objects from the remote media resources.

15 The above and other features of the invention including various novel details of construction and combinations of parts, and other advantages, will now be more particularly described with reference to the 20 accompanying drawings and pointed out in the claims. It will be understood that the particular method and device embodying the invention are shown by way of illustration and not as a limitation of the invention. The principles and features of this invention may be 25 employed in various and numerous embodiments without departing from the scope of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

In the accompanying drawings, reference characters 30 refer to the same parts throughout the different views. The drawings are not necessarily to scale; emphasis has instead been placed upon illustrating the principles of the invention. Of the drawings:

- 4 -

Fig. 1 is a schematic block diagram illustrating the context in which the inventive media manipulator operates;

5 Fig. 2 is a block diagram illustrating the interaction between components of the media manipulator according to the invention;

Fig. 3 is an object interaction diagram illustrating the operation of the components of the media manipulator;

10 Figs. 4A, 4B, and 4C show the message formats for transmitting tasks to compute servers;

Fig. 5 is a block diagram showing the programming of the media manipulator using m-script;

15 Fig. 6 is another object interaction diagram showing the order of creation of the components of the manipulator; and

Fig. 7 is a block diagram showing another embodiment of the media manipulator.

20 DETAILED DESCRIPTION OF THE DRAWINGS

Fig. 1 illustrates the context in which the media manipulator 100 operates. In many applications, it is important for users to access remote media resources 108 such as the data servers 104 of content providers on the Internet. These users may be at client computers 110 that are inter-connected by a local area network (LAN) 112. The clients 110 access the media resources 108 through a gateway 114 linking the LAN 112 to the Internet. The user's also require access to the media resources 108 remotely at remote clients 116 through, for example, telephone dial-up connections 118 or through cellular/wireless links 120.

35 The media manipulator 100 is connected into this two-tiered client-server network of computers as a

-5-

middle layer between the clients 110, 116 and the remote data servers 104 of the media resources 108.

Fig. 2 is a block diagram illustrating the internal organization of the media manipulator 100. It comprises six basic components: media flow manager 210, media parser 212, network access layer 214, object switch 216, multiple service plugins 218, and global access cache 220. In one embodiment, these components are implemented as separate software objects that run on a common microprocessor or multiprocessor system.

The media flow manager 210 serves as the principle controller for the media manipulator 100. It has access to the various components and can alter their behavior. It specifies the operations to be formed on the received media objects. It is also the storehouse for the information on the media objects as they are received from the media parser. The media flow manager 210 also tracks the physical resources that are functional and available in the media manipulator and on the surrounding LAN in order to determine to which of the resources the media objects flow.

The network access layer 214 makes the media manipulator 100 accessible through many different types of network devices and the protocols running on top of them. In one implementation, the network access layer communicates through the Internet gateway 114 using the TCP/IP protocol, connects to the compute or data server using the protocol of the local area network 112, and communicates with the clients using either the LAN or the protocols necessary to communicate with the remote clients 116 over low-bandwidth connections 118, 120.

-6-

When communicating with the remote data servers 104 of the content providers, the network accepts the incoming data streams and assembles them into media objects. These media objects are then made available 5 to the media parser 212, object switch 216, and service plugins 218. The media parser 212 analyses all incoming media objects to extract the relevant media types. These media types include executable files, data files, and images, for example. Information 10 concerning the detected media types is forwarded to the media flow manager 210, which decides what operations should be performed on the media.

The object switch 216 supports a number of 15 incoming and outgoing object gates. Media objects enter into the object switch from the network access layer 214 and from the service plugins' output links. The media objects leaving the object switch 216 go into the network access layer 214 and the service plugins' 20 input links. The object switch routes the objects based on the media manager instructions, either directly or indirectly.

The global access cache is an intelligent 25 mechanism that speeds the operation from the perspective of the user at the clients 110, 116. It determines which media objects are most likely to be used in the future and stores them in the fastest available memory. Media objects that are somewhat less 30 likely to be required again are stored in slower memory or a secondary cache. There can be as many levels of the cache as the physical infrastructure allows, and the caching may take place on data servers that are remote from the main computational resources of the 35 media manipulator. This caching minimizes the time

-7-

that different users need to wait for requests to be processed.

The media manipulator 100 is a programmable
5 device. A system administrator can change its behavior
by giving it m-script commands. It is also an
extendable device. By adding new service plugins, new
capabilities can be added to the device. The
construction of the components of the media manipulator
10 allows for redundancy and fault tolerance. A hardware
failure does not bring the entire system to a halt.
The system will keep working and simply notify the
administrator that one of its components needs to be
replaced.

15

Fig. 3 is an object flow diagram illustrating the
communication between the client 110, 116, content
provider's data server 104, and the components of the
multimedia manipulator 100.

20

The first step is the initial connection 1,
Connect, between the client 110, 116 and the media
manipulator 100 via the network access layer 214. The
network access layer 214 accepts this request 2. In
25 one implementation, it accepts by calling a new
incidence of itself such that each incidence of the
network access layer object supports a single
connection outside the media manipulator 100.

30

After establishing the connection, the client
makes a request 4 for a media object. In the typical
example, this will be a universal resource locator
(URL) to a data server 104 of a content provider on the
Internet. The network access layer then calls the
35 media parser 212 and passes the client request 6.

-8-

The media parser 212 looks to two sources for the media object simultaneously. The ProcessURL request 8 is passed to the media flow manager 212, which has knowledge of the contents of the global access cache 220. 5 The parser also issues a request 10, GetPage, to the network access layer.

The media flow manager 212 searches for the object in the cache 220. If the cache returns a cache-miss, 10 the request to the provider has not been delayed waiting for the miss status, whereas in the case of a cache-hit, the request to the provider is simply terminated after verifying the validity of the cached page. Using this scheme, there is little increased 15 latency associated with the use of the manipulator 100 in the worst-case cache-miss scenario.

In the illustrated example, a cache-miss occurred. Thus, rather than supplying the object, the cache 220 20 is prepared 12 to receive the media object, PutInCache. Also, the network access layer 214 connects 14 to the content provider and retrieves 16 the media object or page.

25 As the media object is being received by the network access layer from the content provider 104, the parser begins to parse 17 the object. As parsing proceeds, the parser also begins to update 18 the global access cache 220 with the parsed portions of the 30 object. Simultaneously, the parser begins the reply 20, 22 to the client via the network access layer.

In one implementation, the parser searches for 35 images in the media objects to perform compression or pornography detection, for example. On encountering an

-9-

image, the parser 214 passes a call to the media flow manager to process the image 24 while continuing to parse 26 the media object.

5 The media flow manager 210 gets the image 28 via the network access layer 214. The fact images are not stored with the page but must be separately requested is an artifact of the HTTP protocol. The network access layer 214 then connects 30 to the content provider 104 and retrieves 32 the image.
10

When the image is retrieved, the media flow manager 210 places it in the cache with the other portions of the media object and makes a function call
15 to the object switch to process the image 34. The object switch knows the various service plugins that are available and the actions that must be performed on the media types that are discovered by the media parser, which in this example is an image. When called
20 by the object switch 216 to process 36 the media type, the particular service plugin, or multiple plugins when serial operations are required, retrieves 38 the media type, i.e., image, and performs the desired operation
25 on or processes 40 the image. For example, in one instance, this can be compression or thinning to expedite communication to the client. In another case, it can detect the probability of pornography by detecting the percentage of flesh-tone colors in the picture. Once the processing is complete, the new
30 image or revised media object may be placed 42 in the cache 220 or used in a reply to the client 110, 116.

In many instances, the service plugin functionality will be performed by a separate compute

-10-

server 105. This computer may be directly accessible by the media manipulator 100 or accessible through the local area network 112. Generally out-sourcing this functionality is desirable, rather than running on the 5 same device with the other components of the media manipulator 100, to avoid depriving those other components of processing bandwidth.

When the plugin does utilize the external compute 10 server, it issues a request message. Fig. 4A illustrates the formatting of the message to the compute server. The message has a number of different fields. It has a version field and a length field defining the length of the content. The type field 15 indicates the type of the message, and the message ID is assigned by the network access layer. The source type indicates the media type. In the context of image files, the type indicates whether the image is in a GIF or JPEG type compression format, for example. The 20 source path is the path to where the image is stored in the global access cache 220, to which the compute server has access. The destination type, path length, path, and parameters define the transformed media type and where it is to be sent.

25

Fig. 4B illustrates the reply message from the compute server. It again has version, length, type, and message ID fields. The reply code indicates whether or not the service was successful. The 30 destination type, path length, and path indicate the type of the final image after the transform of the compute server has been implemented and where that final image is stored in the global access cache or otherwise.

35

-11-

Fig. 4C shows the error message issued by the computer server when service was unsuccessful or error occurred. To contain this information, the message has a computer server error code identifying the server and 5 a field holding the reason for the error.

As illustrated in Fig. 5, the administrator or Internet application developer specifies the actions of the media manipulator by supplying an m-script language to the media flow manager 210. This is a quasi-10 configuration, script file which forms a high level programming language of the media manipulator. The following illustrates the general structure of the language with examples showing its use in the media manipulator 100.

15

name := definition

The name of a rule is simply the name itself (without any enclosing "<" and ">") and is separated from its definition by the colon-equal (":=") character.

20 **"literal"**

Quotation marks surround literal text. Unless stated otherwise, the text is case-sensitive.

rule1 | rule2

Elements separated by a bar ("|") are alternatives,
25 e.g.,

"yes | no" will accept "yes" or "no".

{rule1 rule2}

Elements enclosed in parentheses are treated as a single element. Thus, "{elem {foo | bar} elem}" allows
30 the token sequences "elem foo elem" and "elem bar elem".

rule*

-12-

The character "*" following an element indicates repetition. For example, "foo bar*", implies, "foo" followed by zero or more of "bars".

[rule]

- 5 Square brackets enclose optional elements. For example, "foo [bar]" implies, "foo" followed by zero or one of "bar".

The BNF grammar of the m-script is grouped under three logical groups.

10

Basic

| | | | |
|----|----------------|---|-----------------------------|
| | Alphabets | := {abc...zABC..Z} | |
| | Variable-chars | := {abc...zABC...Z-_} | |
| 15 | Numbers | := {0...9} | |
| | Variable-name | := Variable-chars {Variable-chars Numbers}* | |
| | Host-name | := Variable-chars {Variable-chars Numbers ".")*} | |
| | Path-name | := {Variable-chars Numbers ":" "/" "\"" "~" ":"}* Others | := {@#\$%^&*()}{ }- = <,>,} |
| 20 | EOLN | := "\n" | |
| | Comment | := "#" {Variable-chars Others ":" "/" "~" ":"}* EOLN | |

This section describes the basic rules used: Alphabets are composed of letters "a" through "z", "A" through "Z"; Numbers are composed of digits zero through nine. Variables-chars are alphabets, dash ("") and underscore ("_"). A variable name must start with a Variable-char and followed by zero or many variable-chars or numbers. Host-name is similar to variable-name and in-addition can have periods ("."). Path-name is a generic path used for locating files. EOLN is ASCII 13. A comment must start with "#" character and ends with an EOLN.

- 13 -

Generic

m-script := { comment | section }*

Section := section-key {" section-Desc "}"

Section-Desc := section-line*

5 Section-line := section-desc-key "=" section-desc-value [EOLN]

Section := server-section | cache-section | service-section | filter-section | action-section

10 This section describes a generic m-script file. An m-script is a comment or a section. A section must start with a Section-key, followed by a Section-description enclosed in parentheses. The section description is made up of zero or many section lines. A section line
15 starts with a section description key followed by an equal sign ("=") and the section description key's value. There are five types of sections, viz., server, cache, service, filter and action.

20 Detail

Server-section := "server" {" server-sec-desc "}"

Server-sec-desc := server-name-line | server-port-line

Server-name-line := "name" "=" host-name [EOLN]

Server-port-line := "port" "=" numbers [EOLN]

25

A server section starts with the key "server". This section consists of two lines: Name and port lines. The name line specifies the name of the host on which the MM 100 is run. The port line specifies the main port number on which the MM awaits requests from clients.

30 Cache-section := "cache" {" cache-sec-desc "}"

-14-

Cache-sec-desc := cache-clean-line | cache-direc-line
Cache-clean-line := "cleanup" "=" { number | "no" }
Cache-direc-line := "directory" "=" Path-name

5 A cache section starts with the key "Cache". This
section consists of two lines as well: Cache-clean and
directory lines. The cache-clean line specifies the
time interval after which the cache cleaning is
performed. It takes two values: a positive number (time
10 interval in seconds) or the string "no"(implying never
to be cleaned). The directory line specifies the
directory in which the cached files need to be stored.

Service-section := "service" {" Service-sec-desc "}
15 Service-sec-desc := Service -id-line | Service-host-line | Service-port-line
Service-id-line := "id" "=" variable-name
Service-host-line := "host" "=" host-name
Service-port-line := "port" "=" numbers

20 A service section is for service plugins. There must be
a service section for each service that has to be used
by the MM 100. This section starts with the key
"service". The section consists of three lines: Id,
Host and port lines. The id line specifies a user
25 defined identifier that can be used in other sections.
The host and port lines respectively specify the name
of the host and port number on which the service is
available.

30 Filter-scc := "filter" {" filter-desc "}
Filter-desc := filter-object-line | filter-action-line
Filter-Object-line := "object" "=" Filter-Object-Name

-15-

Filter-Object-Name := "image" | "video" | "java"

Filter-Action-line := "action" "=" variable-name

A filter section starts with the key "filter". This
5 section consists of two lines: object and action line.
The object line specifies the name of the object to be
identified and filtered. The action line identifies
the rule to be applied on the object. Currently, the
objects identified are images. In future, objects like
10 video and Java applets can be identified.

Action-section := "action" {"action-desc"}

Action-desc := action-id-line | action-cond-line | action-proc-line

Action-id-line := "id" "=" variable-name

15 Action-cond-line := "cond" "=" Action-cond-exp

Action-cond-exp := [Action-exp-bin-op] Action-exp-var [Action-cond-exp-
op Action-cond-exp]

Action-exp-bin-op := "!"

Action-cond-exp-op := "&&" | "||" | "==" | "!=" | ">" | "<" | ">=" | "<="

20 Action-exp-var := { Filter-Object-Name "." Parameter } | { variable-name
"." "result" }

Parameter := "any" | "transparent" | "animated"

Action-proc-line := "process" "=" Action-proc-exp

25 Action-proc-exp := { variable-name} Method-exp } [Action-connect Action-
proc-exp]

Method-exp := Filter-Object-Name "." Method-name "(" Method-
Param* ")"

Method-name := "replace"

Method-Param := "''' Path-name '''"

30 Action-connect := "&" | "|"

-16-

The action section is the most complicated section. The action sections can be linked to other action sections forming a list of actions to be applied in tandem. The
5 section starts with the key "action". This section consists of three lines: id, condition and process lines. The id, as before, is a user assigned identifier. The condition line specifies a condition when the process has to be performed. The condition is
10 like a standard "C" expression. It uses object's properties (e.g., image.transparent - image that has a transparent bit), or result of other rules (e.g. rule1.result). The process can be a service identifier or another rule identifier. Several identifiers can be
15 connected using action connectors: "&"(and) or "|"(or). The "&"(and) connector implies both the rules have to be applied in succession (e.g.: rule1 & rule2 - implies apply rule1 and then rule2). The "|" (or) connector implies that apply either of the process (e.g.:
20 compress1 | compress2 - implies, apply compress1 or compress2).

An example is as shown below:

```
25 1 #m-script for manipulating HTML files
    2
    3 #listening host name and port
    4 server {
    5   name = center
    30 6   port = 8001
    7 }
    8
    9 #cache parameters
    10 cache{
    35 11   cleanup = no
    12   directory = "/opt/mm/cache/images/"
```

- 17 -

```

13      }
14
15      #compress service server 1
16      service{
5       17      id = compress1
18      host = center
19      port = 7002
20      }
21
10     22      #compress service server 2
23      service{
24      id = compress2
25      host = center
26      port = 7003
15     27      }
28
29      filter{
30      object = image
31      action = rule1
20     32      }
33
34      action{
35      id = rule1
36      cond = image.any && ! image.transparent
25     37      process = compress1 | compress2
38      }

```

| | Line | Explanation |
|----|-------|---|
| | # | A comment line starts with a “#” character. Everything to the end of that line is ignored. |
| 30 | 5 & 6 | The media manipulator listens on the host “center” and on port “8001” |
| | 11 & | The files are cached (global cache) on the server. Keep them longer. Store them in the directory specified. |
| | 12 | Compute server id is “Compress1”. The host address is “center” and is listening on port “7002” |
| | 17-19 | Compute server id is “Compress2”. The host address is “center” and is listening on port “7003” |
| 35 | 30 & | Filter the images and apply rule1 |
| | 31 | |

- 18 -

35 This section is rule1
36 Do the process for any image that is not transparent.
37 Process images by sending to compress1 or to compress2

Example #2

5 Apart from compressing the images, the images can be tested for pornography. For this a service section has to be added and the action section has to be modified. The following m-script accomplishes this.

```
10     1      #m-script for manipulating HTML files
      2      #This compresses the images and detects them for pornography
      3
      4      #listening host name and port
      5      server {
      6        name = center
      7        port = 8001
      8        }
      9
     10     #cache parameters
     11     cache{
     12        cleanup = no
     13        directory = "/opt/mm/cache/images/"
     14        }
     15
     16     #compress service server 1
     17     service{
     18        id = compress1
     19        host = center
     20        port = 7002
     21        }
     22
     23     #compress service server 2
     24     service{
     25        id = compress2
     26        host = center
     27        port = 7003
     28        }
     29
     30     #pornography detect service server 1
     31     service{
```

-19-

```
32      id = porno1
33      host = center
34      port = 7010
35
5       35
36      #pornography detect service server 2
37      service{
38      id = porno2
39      host = center
10     40      port = 7011
41      }
42
43      filter{
44      object = image
15     45      action = all_image_rule
46      }
47
48      action{
49      id = all_image_rule
20     50      cond = image.any
51      process = compress_rule & porno_rule & destroy_rule
52      }
53
54      action{
25     55      id = compress_rule
56      cond = ! image.transparent
57      process = compress1 | compress2
58      }
59
60      action{
30     61      id = porno_rule
62      cond = compress_rule.result == 1
63      process = porno1 | porno2
64      }
35     65
66      action{
67      id = destroy_rule
68      cond = porno_rule.result >= 75
69      process = image.replace("/opt/mm/lib/images/forbidden.gif")
40     70      }
```

| Line | Explanation |
|------|-------------|
| # | |

- 20 -

5 - 8 Server section
11 - 14 Cache section
16 - 28 Compute servers "Compress1" and "Compress2"
31 - 35 Pornography detection service "porno1" is running in "center" and listening on port
 7010
5 38 - 42 Pornography detection service "porno1" is running in "center" and listening on port
 7010
44 - 47 Filter the images and apply all_image_rule
49 - 52 Apply action "all_image_rule" to all images. First apply compress_rule, followed by
 porno_rule and then by destroy_rule.
55 - 59 Apply action "compress_rule" to non-transparent images. Pass the images to either
 compress1 or compress2.
61 - 65 Apply action "porno_rule" to images, if compress_rule returned 1. Pass the
 compressed images to porno1 or porno2.
10 67 - 71 Apply action "destroy_rule" to images, if porno_rule returned a value greater than or
 equal to 75(probability of a pornographic image). Replace the image with
 "forbidden.gif".

Media Flow Manager (MFM)

MFM reads m-script and configures itself and other
components based on the m-script. The MFM can be
15 implemented as a multi-threaded object as shown below:

```
class MFM{  
private:  
    int iPort;  
20    char *strHostName;  
    char *strMFileName;  
    MediaParser *pMP;  
    GAC *pGAC;  
    ObjSw *pOS;  
25    NAC *pNAC;  
    ...
```

- 21 -

```
public:  
    MFM();  
    ~MFM();  
    int Configure(char *strMFileName);  
5     int ProcessURL(char *strURL, ...);  
    int ProcessImage(char *strSrcURL, int iHeight, int iWidth, ...);  
    int CheckCacheUpdate(...);  
    int CreateInstance();  
    ...  
10    };
```

| | |
|------------------------|---|
| Configure(...) | Parses the m-Script file specified and configures the rest of the components. |
| ProcessURL(...) | This is called by the parser, when it encounters a new image. This initiates the cache insertion on GAC. |
| ProcessImage(...) | Mainly invoked by the MediaParser, when it encounters an image tag. |
| 15 CreateInstance(...) | This passes the command to the appropriate object switch. This creates a new instance of the MFM by first copying the internal data structures and then creating a new thread. |

Media Parser - HTML Parser
The media parser can be implemented using generic tools like lex and yacc. The core of the parser can then be
20 packaged to make parser objects.

```
class MediaParser {  
private:  
    MFM *pMFM;  
25    GAC *pGAC;  
    ...  
public:
```

- 22 -

```
MediaParser(MFM *pMFM, GAC *pGAC, ...);  
~MediaParser();  
int AddFilter(int iObjectType, ...);  
int Parse(...);  
5      ...  
};
```

AddFilter(...) Called by the MFM.Configure, adds to the list of objects that the MediaParser has to look for.

Parse(...) This is called by the NAL, when it successfully establishes a connection with the client. This parses the media. When it encounters the object to be filtered, the parser notifies the MFM by invoking the appropriate function.

10 Global Access Cache
The global access cache is a specialized cache system, specifically tuned to keep HTML pages and the images. The images can have multiple versions. These have to be cached
15 separately. The cache is also cleaned regularly as described in the cache section of the m-script.

```
class GAC{  
private:  
20      char *apMainBuckets[MAX_HASH_KEY];  
      int Hash(char *strURL);  
      ...  
public:  
      GAC(MFM *pMFM, char *strPath, ...);  
25      ~GAC();  
      int SearchCache(char *strURL, ...);
```

- 23 -

```
int PutInCache(char *strURL, char *strLocalFilename, FILE *fp, ...);
int UpdateCache(char *strURL, ...);
int GetFromCache(char *strURL, int iKey, ...);
...
5   };

Hash(...)      This is used to create the Hash key based on an URL.
SearchCache(...) This searches the cache for the given URL.
PutInCache(...) First searches the cache(SearchCache()) and if not found, inserts the
10    URL int the cache.
UpdateCache(...) Updates the cache entry with related entries. For example, the URL
entry can be updated with image entries that are related to the URL.
GetFromCache(...) Retrieves an URL or an Image.
```

Network Access Layer

The network access layer for handling HTML pages, primarily
15 deals with HTTP(Hyper Text Transmission Protocol). It
accepts connection from the clients; makes connection to
the content provider; requests and receives pages and
images from the content provider. In addition to these the
layer also provides connection to compute servers.

```
20
class NAL{
private:
    int iPort;
    char *strHostName;
25    int iNumCharsRead;
    int iNumCharsWritten;
    char *strURL;
    ...
public:
30    NAL(MFM *pMFM, MediaParser *pMP, ...);
```

- 24 -

```
~NAL();  
int Listen(char *strHostName, int iPort, ...);  
int Accept(...);  
int Connect(char *strHostName, int iPort, ...);  
5 int AcceptClients(char *strHostName, int iPort, ...);  
int GetImage(char *strHostName, int iPort, char *strURL, ...);  
int GetURL(char *strHostName, int iPort, char *strURL, ...);  
int SendRequest(...);  
int ReceiveReply(...);  
10 ...  
};
```

| | | |
|----|-------------------|--|
| 15 | Listen(...) | Creates a listening port. |
| | Accept(...) | Accepts any client requesting a connect. |
| | Connect(...) | Connects to the specified host and port number. Usually called by the |
| | GetImage(...) | GetImage() or GetURL() Connects to the ContentProvider and requests the image specified by the URL. This is responsible for building the appropriate request header etc |
| | GetURL(...) | Connects to the ContentProvider and requests the page specified by the URL. This is responsible for building the appropriate request header etc. |
| | SendRequest(...) | Sends a formatted message to the compute server. The format of the message is shown in the following section. |
| | ReceiveReply(...) | Receives a formatted message that is a reply to the message sent earlier. |

20

Service Plugin

The service sections describe the various servers available
for the MM. Each service server is an instance of this
object.

25

- 25 -

```
class ServPlugin{
private:
    char *strId;
    int iPort;
5     char *strHostName;
    ...
public:
    ServPlugin(NAL *pNAL, char *strId, char *strHostName, int iPort, ...);
    ~ServPlugin();
10    int Request(char *strSrcPath, char *strDestPath, ...);
    ...
};

Request(...) This initiates the request through the NAL. NAL sends the formatted
               message to the appropriate Compute Server.
```

15

Object Switch
The object switch interfaces the MFM and the service
plugins. The object switch mostly implements the rules
specified in the action section of the m-script, as
20 instructed by the MFM.

```
class ObjSw{
private:
    MFM *pMFM;
25    GAC *pGAC;
    ServPlugin *aSP; //array of service plugins
    ActionList *alAction; //linked list of actions

public:
```

- 26 -

```
ObjSw(MFM *pMFM, GAC *pGAC, _);
~ObjSw();
int AddServicePlugin(ServPlugin *pSP, _);
int AddAction(char *strId, char *strCond, char *strProcess, _);
5    int ProcessImage(_);

};
```

AddServicePlugin() This is invoked by the MFM during configuration phase. This adds the service plugin to its internal list.
10 AddAction() This is also invoked by the MFM during the configuration phase. This adds the actions specified in the m-Script
ProcessImage() Invoked by the MFM, this executes the actions in the specified order.

Compute Server
15 The compute server executes as a separate processor or on a different machine itself. It can be implemented as an object as well.

```
class CompServ{
20 private:
    int iPort;
    char *strHostName;
    ...
public:
25    CompServ();
    ~CompServ();
    int ReceiveRequest(char *strSrcPath, char *strDestPath, ...);
    int ProcessRequest(...);
    int Reply(...);
```

-27-

...

};

- | | | |
|---|---------------------|---|
| 5 | ReceiveRequest(...) | This receives the formatted message. |
| | ProcessRequest(...) | This processes the request. The user can extend the compute server by adding capabilities to this method. |
| | Reply(...) | Sends the reply. |

The compute server can also use the NAL to send and receive messages.

10

Fig. 6 is an object interaction diagram showing the order of creation of the objects/components of the manipulator 100 and the order in which the m-script is processed or read. Of note is the fact that the object switch 216 is called after service plugins 218. This order ensures that the services are all declared. AddAction takes the pointer to those service plugins, and AddServicePlugin identifies the compute server executing the plugin, its host name, and its port. ObjSw ensures the GAC 220 may be updated by the object switch with the results of the service, once executed.

Fig. 7 illustrates another embodiment of the inventive media manipulator 100. The media manipulator described in the previous sections was used as an intermediate processor between the client 106, 116 and the content provider server 104. In this alternative embodiment, an additional, stripped down tunneler version of the manipulator 100' can be used to interact between the client 106, 116 and the media manipulator 100 as described previously. These two instances of the manipulator 100, 100' can now perform in unison to further enhance the user experience.

-28-

The tunneler media manipulator 100' and the media manipulator 100 exchange a compressed format suitable for the transmission over a low-bandwidth connection, while the tunneler 100' and the browser(client) 5 exchange information in the client's native format. Apart from these, the client 106, 116 can be inside a firewall f and still use the services of a main media manipulator 100, which may be outside the firewall f. The tunneler 100' can also be used to set various 10 options such as compression quality, specific to the client's need. These options are forwarded to the main media manipulator 100 along with the client's request. The main media manipulator 100 can categorically act on both the tunneler's and client's request.

15

Apart from compressing images, the tunneler 100' and main media manipulator 100 combination can be used to compress the HTML page itself. The HTML page is a media, and if the service is available to compress it, the m-script can be modified appropriately to send the 20 page to the text-compress-plugin before sending towards the client. The tunneler can intercept this and decompress the page.

25

The tunneler 100' has following components of the media manipulator: 1) media flow manager 210, 2) media parser 212, 3) object switch 216, 4) network access layer 214, and 5) service plugin 218. It does not have the global access cache 220. The service plugin in the 30 tunneler 100' is the compliment of what is used in the media manipulator to decompress the images.

-29-

While this invention has been particularly shown and described with references to preferred embodiments thereof, it will be understood by those skilled in the art that various changes in form and detail may be made therein without departing from the spirit and scope of the invention as defined by the appended claims.

-30-

CLAIMS

What is claimed is:

- 5 1. A middle-ware computing system comprising:
 - a network access system that supports communications with media resources and client computers; and
 - a media manipulation system that operates on media objects received from the media resources via the network access system prior to forwarding the media objects to the client computers.
- 10 2. The computing system described in Claim 1, wherein the media manipulation system comprises:
 - a parser that identifies different media types within the media objects; and
 - service devices that operate on the media types.
- 15 3. The computing system described in Claim 2, wherein the parser searches for images in the media objects and service devices include an image compressor for performing data compression on the images.
- 20 4. The computing system described in any of Claims 2-3, wherein the parser searches for executable files in the media objects and service devices include a virus scanner that searches for computer viruses in the files.
- 25
- 30

-31-

5. The computing system described in any of Claims 2-4, wherein the parser searches for images in the media objects and service devices include a pornography detector for assessing a probability
5 that the images are pornographic.
- 10 6. The computing system described in any of Claims 2-5, wherein the parser searches for data files in the media objects and service devices include an format converter for changing a format of the data files.
15 7. The computing system described in any of Claims 2-6, wherein the media manipulation system further comprises an object switch that passes the media types to the service devices to determine operations performed on the different media types.
20 8. The computing system described in any of Claims 2-7, wherein the media manipulation system further comprises a media flow manager that reassembles the media objects for forwarding to the clients after the manipulation of the media types.
25 9. The computing system described in Claim 8, further comprising a cache that stores media objects, the media flow manager receiving requests for media objects and checking for the presence of the media objects in the cache to preclude obtaining the objects from the media resources.
30

-32-

10. A middle-ware computing system comprising:
 - a network access system that supports communications with media resources to obtain media objects from client computers;
 - 5 a parser that identifies different media types within the media objects;
 - service devices that manipulate the media types;
 - an object switch that passes the media types to the service devices to determine operations performed on the different media types; and
 - 10 a media flow manager that reassembles the media objects for forwarding to the clients after the manipulation of the media types.
- 15
11. The computing system described in Claim 10, further comprising a cache that stores media objects, the media flow manager receiving requests for media objects and checking for the presence of the media objects in the cache to preclude obtaining the objects from the media resources.
- 20
12. A method for facilitating transmission of media objects between media resources and client computers, the method comprising:
 - receiving requests for media objects from the client computers to the media resources;
 - 30 obtaining the media objects;
 - manipulating the media objects;
 - forwarding the manipulated media objects to the client computers.
- 25
- 30
- 35

- 33 -

13. The method described in Claim 12, wherein manipulating the media objects comprises:
 - identifying different media types within the media objects; and
 - 5 performing separate operations on the different media types.
14. The method described in Claim 13, wherein the step of identifying different media types comprises searching for images in the media objects and the step of performing operations comprises data compressing the images.
15. The method described in any of Claims 13-14, 15 wherein the step of identifying different media types comprises searching for executable files in the media objects and the step of performing operations comprises scanning the files for computer viruses.
- 20 16. The method described in any of Claims 13-15, wherein the step of identifying different media types comprises searching for images in the media objects and the step of performing operations comprises assessing a probability that the images 25 are pornographic.
17. The method described in any of Claims 13-16, 30 wherein the step of identifying different media types comprises searching for data files in the media objects and the step of performing operations changing a format of the data files.

- 34 -

18. The method described in any of Claims 13-17, further comprising reassembling the media objects for forwarding to the clients after the manipulation of the media types.
19. The method described in any of Claims 13-18, further comprising routing the media types to form successive operations on the media types.
20. The method described in any of Claims 13-19, further comprising caching media objects that have been received from the media resources and later obtaining the media objects from the cache.
21. The method described in Claim 20, wherein the step of obtaining the media objects comprises requesting the media objects from the media resources while checking for the objects in a cache; and obtaining the media objects from the cache if present.

| <p>(54) Title: NETWORK BASED PROGRAMMABLE MEDIA MANIPULATOR</p> | | | |
| <p>(57) Abstract</p> <p>The media manipulator is a middle layer between the clients (110, 116) and the remote data servers (104) in the common client-server organization. It transforms the network into a more flexible three-tiered configuration. Requests generated by the clients (110) for media objects from media resources are routed to the media manipulator (100). It processes the requests and determines if the media objects may be found locally, either cached (220) in the media manipulator (100) itself or in the local data servers (106). When the media objects are obtained, the media manipulator (100) can be used to perform operations on those objects such as format translations, to apply protective mechanisms for the clients (110), to speed communications between the remote servers (104) and the clients (110), or perform compute operations for the clients (110). In one example, a parser (112) of the manipulator (100) searches for images in the media objects so that service devices (218) can be called to perform data compression or pornography detection on the images. The parser can also search for executable or data files in the media objects and to perform virus scanning or format conversion, respectively.</p> | | | |

INTERNATIONAL SEARCH REPORT

International Application No
PCT/US 97/10758

A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 H04L29/06

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 6 H04L

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

| Category ° | Citation of document, with indication, where appropriate, of the relevant passages | Relevant to claim No. |
|------------|---|---|
| X | EP 0 669 587 A (AT & T CORP) 30 August 1995 see column 4, line 20 - column 5, line 14; figure 1 see column 7, line 13-34; figure 2 see column 9, line 17-29 see column 16, line 39-51 --- A THAU R: "Design considerations for the Apache Server API" COMPUTER NETWORKS AND ISDN SYSTEMS, vol. 28, no. 11, May 1996, pages 1113-1122, XP002046988 see paragraph 4 --- | 1,12 2,3,7,8, 10,13, 14,18 2,10,13 -/- |
| A | | |

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents :

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

T later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

& document member of the same patent family

7

Date of the actual completion of the international search

20 November 1997

Date of mailing of the international search report

18.12.97

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2
